

OBSERVATORY OUTLINE
31 OCT 2015

- Location:** 29° 50' 13" N 29.8369° N EL89qu
82° 37' 17" W 82.6214° W
53 ft (16 m) MSL
- TFD Array:** Two square arrays on a NS line, eight 30-foot TFD elements, beam steering in 5° increments NS and 15° increments EW.
16 MHz HPBW at zenith: 18° NS x 40° EW
20 MHz HPBW at zenith: 15° NS x 35° EW, D ≈ 14 dBic
24 MHz HPBW at zenith: 12° NS x 30° EW
32 MHz HPBW at zenith: 8° NS x 20° EW
- Receivers:** 1 x Dual Polarization Spectrograph (DPS)
24 x 7 x 365 unattended operation
16–32 MHz, simultaneous (correlated) RCP and LCP
300 channels per polarization (600 total)
Swept frequency, selectable 7.5, 15, 30, 60 kHz pre-detection BW
~ 6.7 sweeps/sec, integration time = 500 μs per sample
Frequency resolution = 53 kHz, Δt = 150 ms
- 1 x Tunable Wideband Receiver (TWB) Mark III
Attended operation only
Tunable from 16 to 32 MHz, RCP or LCP
2 MHz IF BW direct to high speed digitizer
FFT post-processing, RBW = 4.88 kHz, Δt = 205 μs
- 1 x FS-200B radio spectrograph
24 x 7 x 365 unattended operation
16–26 MHz, RCP or LCP, 200 channels
Swept frequency, 30 kHz pre-detection BW
~ 10 sweeps/sec, integration time = 500 μs per sample
Frequency resolution = 53 kHz, Δt = 150 ms
- 2 x Radio Jove receivers
24 x 7 x 365 unattended operation
~ 20.1 MHz, uncorrelated RCP and LCP
7 kHz RF BW folded via direct conversion into
a baseband 3.5 kHz pre-detection audio BW
Integration time = 100 ms per sample

- Sensitivity:** Formal sensitivity calculations and measurements have not been made. A rough estimate considering only the number of dipoles is a 20 MHz on-axis and at zenith 3σ sensitivity on the order of 100 kJy. In the upper HF band, system noise is dominated by the galactic background emission. All receivers presently in use have noise figures between 6 and 8 dB, making their internal noise of little concern given the modest losses between the TFD array and the receivers.
- Timing:** All radio telescope data collection systems use a PC's internal clock to apply timestamps to the data. Each PC runs a service, Meinberg NTP daemon, to keep its system clock within a few milliseconds of UTC using Network Time Protocol (NTP). The NTP server is a GPS-ntp-pi stand-alone unit using GPS and GLONASS signals to determine and provide the correct time on the local network. Future work includes upgrading the spectrographs to a GPS-based hardware system with firmware modification to keep the start of each frequency sweep disciplined to within a hundred nanoseconds of UTC.
- Calibration:** All radio telescope systems are calibrated in terms of antenna temperature using a noise source of known temperature calibrated against a 5722 noise diode. An automatic calibrator runs a step calibration on all receivers at 2350 UTC every day. The step cal runs in 17 steps of 5 seconds each separated by 3 dB, ranging from 1.1 kK to 52 MK equivalent antenna temperature.
- Computers:** Three identical PCs are used to record data from the receivers. Each has a 2.4 GHz AMD Opteron dual-core processor, 4 GB RAM, and a 1 TB hard drive. All run Windows XP SP3. All are connected to the observatory LAN.
- Internet:** The observatory has internet access via a 6 Mbps DSL connection. This connection allows the Radio Sky Pipe (RSS) and Radio Sky Spectrograph (RSS) software to serve data to interested remote observers.
- Power:** The receivers, computers, and network hardware are fed by three 1.5 kVA battery backup units providing at least 15 minutes of power if the AC mains fail.
- Operations:** Several radio telescopes operate all day, every day (see "Receivers" above). Useful Jupiter observations are made any time Jupiter is within 3.5 hours of transit.

Juno Support

AJ4CO Observatory (Dave Typinski) will support the Juno ground-based coordinated observations campaign with the following instruments.

Dual Polarization Spectrograph (low resolution)

The DPS will continue to make continuous Jupiter observations. The data will be made publicly available using the VESPA archive, with the conversion to CDF format being done on the VESPA server. Data will be available within 24 hours after the end of each day's observing run.

Tunable Wideband Receiver (high resolution)

The TWB will be operated manually as needed to support the ground-based coordinated observations campaign. Data will be available on an as-requested basis due to the size of the data files produced. Raw time-series waveform data will be available within 24 hours. Processed data (time/freq dynamic spectra) will be available after several days processing time.

Find the magnetic declination at your location

What is Magnetic Declination?

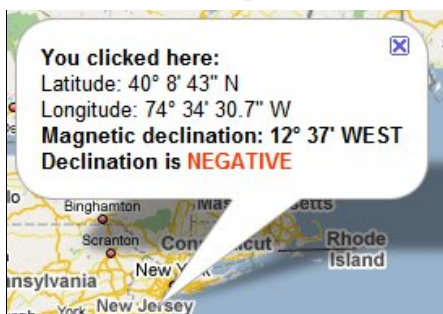

Did you know that magnetic compass does not always point to North? Actually, there are only a few locations on Earth where it points exactly to the True (geographic) North. The direction in which the compass needle points is known as Magnetic North, and the angle between Magnetic North and the True North direction is called **magnetic declination**.

Magnetic declination varies both from place to place, and with the passage of time. As a traveller cruises the east coast of the United States, for example, the declination varies from 20 degrees west (in Maine) to zero (in Florida), to 10 degrees east (in Texas), meaning a compass adjusted at the beginning of the journey would have a true north error of over 30 degrees if not adjusted for the changing declination. The magnetic declination in a given area will change slowly over time, possibly as much as 2-25 degrees every hundred years or so, depending upon how far from the magnetic poles it is. Complex fluid motion in the outer core of the Earth (the molten metallic region that lies from 2800 to 5000 km below the Earth's surface) causes the magnetic field to change slowly with time. This change is known as secular variation. Because of secular variation, declination values shown on old topographic, marine and aeronautical charts need to be updated if they are to be used without large errors. Unfortunately, the annual change corrections given on most of these maps cannot be applied reliably if the maps are more than a few years old since the secular variation also changes with time in an unpredictable manner.

If the compass at your place is pointing **clockwise** with respect to the True North, declination is **positive** or **EAST**

If the compass at your place is pointing **counter-clockwise** with respect to the True North, declination is **negative** or **WEST**

Negative declination (WEST)

Positive declination (EAST)

How can we calculate declination at any given place?

One way would be to use declination maps. Unfortunately because of secular variation, declination values are constantly changing. When printed maps were the only way of getting this information, the declination values were somewhat out of date by the time the maps got to the general public.

Another way would be to perform a prediction. This should be based on a world-wide empirical model of the deep flows. This [web page](#) operated by the National Geophysical Data Center (NDGC) offers a pretty good value for declination. The model reflects a highly predictable rate of change, and will usually be more accurate than a map, and almost never less accurate.

The best way however is to use [the current web site](#), which offers in a graphical format using Google Maps API the computed declination for any place on Earth. The algorithm implements the [World Magnetic Model WMM2015](#).
